[#synergism hypothesis](#) [#progressive evolution theory](#) [#evolutionary biology](#) [#complex adaptive systems](#) [#origins of biological complexity](#)

The Synergism Hypothesis proposes a groundbreaking theory of progressive evolution, highlighting how cooperative interactions and mutual benefits among components drive the emergence of increasing complexity within biological systems. This framework offers a unique perspective on the mechanisms underlying the development of new organizational levels throughout evolutionary history.

Anoles are a group of closely related lizards that occupy diverse habitats and niches.

The islands of the Caribbean are home to 150 different species of anoles.

Most Caribbean anole species likely evolved from a single colonizing species over millions of years.

Changes in some traits keep species reproductively isolated.

One such trait is the colorful flap of skin, or dewlap, under lizards' throats.

What causes dewlaps to change?

Once reproductively isolated, different species may come to occupy different niches in their environment.

Over many generations, lizards' bodies will change as they adapt to their new niches.
