Embryonic folding is the process of converting the embryo from a flat disc, into a cylinder.

This cylinder consists of three main layers, derived from the trilaminar embryonic disc: the endoderm in the center, the ectoderm on the outside, and the mesoderm, which is found between the two layers.

The gut tube is divided into three main parts: the foregut, midgut, and hindgut.

The caudal end of the hindgut is also temporarily closed by a membrane, called the cloacal membrane, which separates the upper and lower parts of the anal canal.

The cloacal membrane ruptures during the seventh week of development to form the urogenital and anal openings.
