ANSWER D: Dialysis machines have evolved since their initial frequent use in the 1960s. These early machines were replaced by the so-called hollow fiber dialyzer, which is the type in use today. In this model, the blood flows through tiny hollow tubes (fibers) while the dialysate flows around the outside of these fibers. Biocompatible membranes, sophisticated alarms, and automatic functions characterize the modern dialyzer.

ANSWER A: Diabetes mellitus is the commonest cause of chronic renal failure (CRF) in the United

States. Because of the obesity epidemic, type 2 diabetes (90% of diabetic patients) is on the rise, and thus, there may be even more cases of CRF in the future.

ANSWER A: Ferritin is the main storage protein for iron, required for hemoglobin synthesis, and is usually low in iron deficiency anemia. Most patients with chronic renal failure are anemic, usually from inadequate erythropoietin production by the kidney or bleeding, often gastrointestinal, or both.

ANSWER B: In hemodialysis, both diffusion and osmosis occur. The dialysate is prepared with solutes (e.g., ions, glucose) to achieve desired levels in the blood. More efficient exchange of fluid and solute is obtained if the two fluids flow in opposite directions, a so-called countercurrent exchange.
